I. Introduction

This document describes a set of signal-processing algorithms, as implemented by the Computer Engineering Research Laboratory at Georgia Tech. The routines are presented as a representative collection of operations for processing Infrared Focal-Plane Array signals.

For the purposes of testing and dissemination, each algorithm is presented as a stand-alone FORTRAN program. These programs are based upon a core *harness* routine which supports the input/output of a common data format (Georgia Tech Algorithm Evaluation Data Format - described in the Harness section). The modular implementations offer several benefits:

- simplification of the generation of test vectors for the verification of alternate implementations
- capability for testing various algorithm combinations, without re-compilation
- support for multiple language and/or processor-platform implementations

II. Harness

A. Description

The *Harness* program shown below is the basis of the input/output methodology used by all of the routines in this document. The code implements a simple Pass-Through module which reads a data stream, picking off the FPA pixel data, and writing the data onto an output data stream.

The Georgia Tech Algorithm Evaluation Data format is a simple ASCII text representation of a data stream. The data stream has two major components - the *Field Header* and the *Field Data*. The harness of each module processes the data stream by reading each line and checking for Field Headers which are relevant to that module. Any lines which are not relevant, or unrecognized, are immediately placed upon the output data stream. As soon as a relevant Field Header is recognized, the Field Data which follows is processed in a manner which is appropriate to that module and Field Header. This scheme provides for the chaining of modules output-to-input, without either module requiring knowledge of all, or any, of the other module's data formats. In typical use, controls for many modules could be included in a single data stream; each module would only process data intended for it. For example, suppose a test setup was composed of the following pipeline:

Input data stream ----> Spatial Filter ----> Simple Threshold ----> Output Data Stream

The data stream might appear as follows:

Input Data Stream	Description	Used by	Action
Dimensions 128	Field Header Field Data	Spatial Filter and Simple Threshold	input
Simple Thresholding Limits 0 256	Field Header Field Data	Simple Threshold	input
Pixel Data 99 93 ... 81 76	Field Header Field Data Field Data	Spatial Filter and Simple Threshold	input, modified
End	Field Header	Spatial Filter and Simple Threshold	input

Output Data Stream	Description	Generated by	Action
Dimensions 128	Field Header Field Data	Spatial Filter and Simple Threshold	copied to output data stream
Simple Thresholding Limits 0 256	Field Header Field Data	Simple Threshold	copied to output data stream
Simple Thresholding Statistics 0 256 1024	Field Header Field Data	Simple Threshold	generated, then placed on output data stream
Pixel Data 99 93 ... 81 76	Field Header Field Data Field Data	Spatial Filter and Simple Threshold	modified, then placed on output data stream
End	Field Header	Spatial Filter and Simple Threshold	copied to output data stream

III. Non-Uniformity Compensation

A. Description

The non-uniformity compensation algorithm provides a pixel-by-pixel correction of the actual pixel response to the desired response. The current algorithm uses up to a five-point, piecewise-linear correction to the pixel intensity. The correction is determined by sending a specified number of calibration frames through the process. Each of the calibration frames will have been generated by exposing the focal-plane array to a known intensity so that a desired pixel intensity is expected at each pixel.

Dead, or inadequately responsive, pixels are assumed to have been marked by another module and, during processing, they are replaced by the intensity of the previous pixel.

After calibration is performed, the algorithm enters the processing phase. For each pixel which is to be processed, it is first determined if it is a dead pixel. For normal pixels, the calibration intensities are searched to determine which section should be used for correction. After the section is determined, a linear interpolation is performed using the input pixel intensity to interpolate between the desired responses.

IV. Spatial Filtering

A. Description

The spatial filtering algorithm performs a convolution of the image with a 3x3 coefficient mask. This implementation supports a four point symmetric mask. Separate masks are used for the edge pixels since not all of the pixels which are needed are defined. This allows more general application of boundary conditions than would be available if the undefined pixels were treated as zeros and the same mask was used.

Since the filter allows negative coefficients in the mask, it is possible to generate negative output intensities. The coding allows the intensity to be output limited to a positive range.

V. Temporal Filtering

A. Description

The temporal filtering algorithm provides a pixel-by-pixel infinite impulse response (IIR) filtering of the sequence of images which are sent through the process. This implementation allows up to a fourth-order filter.

B. Data Fields

Action	Field Header	Field Data	Data Type
input	<i>Dimensions</i>	FPA dimension	Integer
input	<i>Temporal Filtering Limits</i>	Lower limits	Integer
		Upper Limits	Integer
modify	<i>Pixel Data</i>	Pixel data array	Integer [1..Dimension] [1..Dimension]

VI. Thresholding

The thresholding algorithm is used to partition the image into points which are of interest and those that are not of interest. Pixels are zeroed if they are not of interest. A pixel is passed if the intensity is above a calculated lower threshold value and below a fixed upper threshold value. The lower threshold supports two of the modes which are in the Georgia Tech VLSI design. This includes a simple, fixed threshold and an adaptive threshold based on the average and first central absolute moment of the surrounding eight pixels.

IX. Clustering & Centroiding

A. Description

The clustering algorithm forms connected sets of pixels based on the surrounding pixels. Two pixels are elements of the same cluster of pixels if they are one of the eight nearest neighbors of each other. The centroiding algorithm calculates the area centroid and the intensity weighted centroid of the clusters specified by the clustering algorithm.

B. Data Fields

Action	Field Header	Field Data	Data Type
input	<i>Dimensions</i>	FPA dimension	Integer
input	<i>Pixel Data</i>	Pixel data array	Integer [1..Dimension] [1..Dimension]
output	<i>Clusters</i>	Cluster count	Integer
output	<i>Centroids</i>	Vector of the following repeated Cluster count times	
		Area centroid (X)	Integer
		Area centroid (Y)	Integer
		Intensity centroid (X)	Integer
		Intensity centroid (Y)	Integer
		Area in pixels	Integer
		Total cluster intensity	Integer
